ADC Team 02 - Repo Setup Summary

https://github.com/benjamincollu/ADC-team02

What is already done

- **Robot model** - the Unitree G1 is in the repo and tested: it loads and runs in MuJoCo.
- **RL pipeline** - the instructor's working throw pipeline (envs/ + scripts/) is copied in. Our ball-drop task is a small modification of it, so we build on this instead of starting from zero.
- **Starter code** - commented example scripts in src/ (baseline, environment with reward, training, evaluation) to learn from.
- **Lectures** - all 8 camp lecture files are in docs/lectures/.
- **Task documents** - Task 1 and Task 3 docs are pre-written in docs/, matched to the scoring rubric. We only need to fill in our numbers.
- **Key rules** - ball is 4 cm / 50 g (fixed). The target zone is OURS to define and justify.

How to get everything (each member)

1. Accept the collaborator invite from Benjamin (check email).

2. In a terminal:

```
git clone https://github.com/benjamincollu/ADC-team02.git
cd ADC-team02
pip install -r requirements.txt
```

3. Test it - this should open the robot in a MuJoCo window:

```
python scripts/view_g1.py
```

(The robot falls over after a second - normal, nothing is controlling it yet.)

What we do next

1. Agree on success metrics (target zone size, success rate) and put them in docs/task1_task_definition.md.

2. Generate the ball scene: scripts/inspect_g1_bodies.py, then scripts/create_g1_throw_scene.py.

3. Change the reward from "throw far" to "drop about 35 cm in front".

4. Run the baseline, then the first training run, then make the comparison graphs.
